Goal

- To predict the next few frames of the video using a Graph Neural Network for spatio-temporal graphs.
- To know about the nodes a few frames later.

How to proceed?

- An image can be represented as graphs by dividing the image into regions and the neighboring regions, which are interconnected.
- The video consists of multiple frames. Using the above methods, the frame can be converted into a graph.
- The multiple frames add the temporal aspect to the graph. Hence, the graph generated from the number of frames is a spatio-temporal graph.

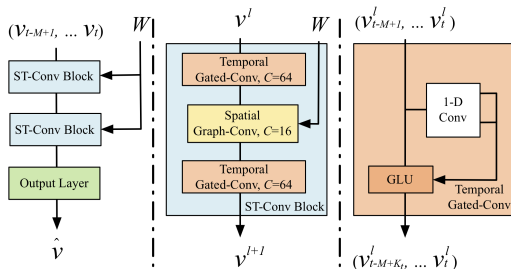

- Since there are large amount of video data are captured, so Video summarizing used to condenses the original video into a short summary while preserving the main content.
- Lots of video summarizing approaches have been proposed but, fully convolutional structure on time axis approach have gained significantly.
- Forecasting traffic speed, volume or the density of roads in traffic networks is fundamentally important in a smart transportation system. We can address the traffic prediction problem by using STGNNs.
